1. What do all the methods (`move()`, `special_move()`, `use()`) in the previous activities have in common?

Answer: They all share the exact same method name within their respective groups of different classes, allowing them to be called uniformly regardless of the object type.

2. How does this activity show polymorphism in a gaming context?

Answer: It shows that game engines or systems can handle completely different entities like different character classes or inventory items using an organized function call without needing complex if and else tests.

3. Can you think of other examples where the same action behaves differently depending on the character or item?

Answer:

An `.equip()` method that equips a sword to a hand slot, armor to a body slot, or a ring to a finger slot.

An `.attack()` method where a boss performs a heavy stomp, a wizard shoots a fireball, and an assassin launches a stealth strike.
